

On Page 8, before the first full paragraph, please insert the following paragraphs:

B2  
W 7/03  
--In the publication of G. Buonanno et al. "The influence of reference condition correction on natural gas flow measurement" in the british magazine "Measurement vol. 23, No. 2 dated 1<sup>st</sup> march 1998 (published of the Institute of Measurement and control, London) on the pages 79-81 is indicated a procedure for determination on the conversion of gas volumes, in which the compressibility factor Z ist determined iterational according to the procedure SGERG-88 und afterwards the parameters  $\xi$  and  $\chi$  are calculated. These parameters are mathematically directly connected with the input quantities pressure p, temperature T an the amounts of substances.

Further on in the U.S. Patent No. 4,958,076 and the U.S. Patent No. 5,822,058 photometric devices with filtering units are known.--

On Page 8, please replace the third full paragraph with the following paragraph:

B3  
--The solution of the object according to the invention results in respect of the procedures from the characterising features of the claims 87 respectively 94 in accordance with the features of the associated pre-characterising part. The solution of the object according to the invention results in respect of the devices from the characterising features of claim 98 in accordance with the features of the associated pre-characterising part. Further advantageous embodiments of the invention result from the respective dependent claims.--

On Pages 8-9, please replace the last paragraph bridging pages 8 and 9 with the following paragraph:

--The invention concerns to a first procedure according to claim 87, with which the

134 determination of the quality of gas of a probe gas, in particular a burnable gas, is carried out based on a spectrum of the probe gas determined under operating conditions by means of infrared spectroscopical measurement procedures. Herein the quality of gas of a probe gas is determined in such a way according to the invention, that in a first step of the procedure the amounts of substances  $x_i$  of the components of the probe gas at operating conditions are determined out of the spectrum, where after default values for compressibility factor  $K$  and real gas factor  $Z_n$  are preset for calculation of the wanted compressibility factor  $K$  and than out of quantities at operating conditions of the probe gas as well as from the amounts of substances  $x_i$  and substance specific quantities such as calorific values per sort of molecule of the components and the respective masses of molecules, and taking into account of the selected default values for compressibility factor  $K$  and real gas factor  $Z_n$  the needed input quantities for the determination of the compressibility factor  $K$  are determined. These input quantities are used, to calculate the compressibility factor  $K$  by means of standard-arithmetic procedures. In a further step of the procedure an iterative calculation in the way of an iterative recalculation of the input quantities is carried out with the determined value for the compressibility factor  $K$  as long, until the value of the compressibility factor  $K$  converges. There from the volumetric standard calorific value  $H_{v,n}$  and the standard density  $\rho_n$  can be calculated. In the case of converging the needed quantities compressibility factor  $K$ , standard calorific value  $H_{v,n}$  and the standard density  $\rho_n$  for determination of the quality of gas of a probe gas are known and can be used respectively for example for the calculation of the energy content of the transported gas. At each iteration the just determined value for the compressibility factor  $K$  is put back again into the equations for

B4  
concl'd

calculating the input quantities of the standard-arithmetic procedure and a new iteration step is carried out. By means of this procedure starting with the determination of the amounts of substances  $x_i$  out of the recorded spectrum and the iteration procedure with the help of the default values for the compressibility factor  $K$  and real gas factor  $Z_n$  after a respective number of iteration steps the really existing values for the compressibility factor  $K$  and there from than the values for standard-calorific value  $H_{v,n}$  and the standard density  $\rho_n$  in the probe gas can be determined with adequate accuracy. In this way the compressibility factor  $K$  is determined out of the spectroscopical measurable quantities in operation conditions as well as out of the default values for the compressibility factor  $K$  and real gas factor  $Z_n$  and the real gas calculation itself can be carried out with standard-arithmetic procedures and these arithmetic procedures itself are again iterative procedures. --

---

On Page 14, for the second full paragraph, please substitute the following paragraphs:

---

B5

--Also it may be thinkable, that the default values for compressibility factor  $K$  and real gas factor  $Z_n$  are taken from a characteristic diagram, that describes the influence of the pressure  $p_b$  at operating conditions and the temperature  $T_b$  at operating conditions for a known composition of a gas similar to the composition of the probe gas. As described before for the procedure according to claim 87, in this way good starting values as a good first approximation for the compressibility factor  $K$  and the real gas factor  $Z_n$  can be determined, which contributes to a fast convergence also of this procedure according to the invention.

By  
concl'd

The invention concerns furthermore to a generic photometric device for the determination of a transmission spectrum of a probe gas, especially for carrying out one of the procedures according to claim 87 or claim 94.--

--Such a generic device can be developed further, if the spectral switch unit shows a chopper arrangement, which transmits because of their selective transmission behaviour only specific spectral regions of the spectrum in the measurement radiation caused by the probe gas to the radiation receiver. In this way the chopper arrangement is be provided with an aperture with a spiral opening, in which the release of the regions of the wavelength of the measurement radiation is caused continuously for the whole spectrum. By this means also compositions of probe gases can be determined, whose spectrums have to be captured over wide regions, also a higher flexibility for the evaluation of the spectrums can be obtained by this.

In this way in further development the chopper arrangement can be provided with such a transmission behaviour, that the transmitted spectral regions are suitable for the further evaluation

Bb  
concl'd

by procedures of the direct spectral evaluation (DSA). By means of the chopper arrangement only that part of the whole spectrum is measured, which is of interest for the determination of the quality of gas for example of a probe gas of typical composition at all und beneath with simple mechanical means allows an exact selection of these spectral regions. Also such a chopper arrangement is build up easily and mechanically solid and insensitive.--

B8

--A multivariate analysis (MVA), as outlined in the literature (DVGW-worksheet 486), delivers the volumetric amounts of substances of the gas components at operation conditions. The here presented procedure according to claim 87 describes, how moreover with these data the standard calorific value  $H_{v,n}$ , the standard density  $\rho_n$  and the compressibility factor  $K$  can be ascertained.--

---

On Pages 25-26, for the paragraph bridging pages 25-26, please substitute the following paragraph:

B9  
--With the procedure according to claim 94 by means of a spectral weighting function the spectrums can be evaluated directly without detailed resolution of the individual gas components. The specification of the calorific value  $H_{v,b}$  at operation conditions according to this procedure is lined out in the patent application DE 198 38 301.0. The volumetric amount of substance of  $CO_2$  at operating conditions can be evaluated as separate absorption band according to common spectroscopic procedures.--

On Page 26, for the first full paragraph, please substitute the following paragraph:

B10  
--Vital component of the here introduced procedure according to claim 94 is the spectral measurement of the density  $\rho_b$  at working conditions, therefore also the convolution of the spectrum with a spectral function is used. The physical background of the procedure is herein, that each binding of the infrared active gas components contribute for extinction and so represents the mass of the partners of the binding in the spectrum. The frequency of oscillation of the binding and therewith their spectral location depends on the reduced mass of the partners of the binding. Therewith the spectrum contains in its amount and its spectral distribution at appropriate evaluation information for the determination of the density of the gas.--

On Pages 26-27, for the paragraph bridging pages 26-27, please substitute the following paragraph:

B11

---

--In the figures 2a and 2b the flows of the two-stage iterative procedure according to the above mentioned equations are illustrated once more precisely. In the figure 2a is represented the principal flow of the calculation of the procedure according to claim 87 with the both alternative iterative procedures AGA8-92DC and GERG88, which start from the results of the multivariate analysis (MVA) by means of the ascertained spectrum. In the figure 2b is represented however the principal flow of the calculation of the procedure according to claim 8, that starts from the results of the direct spectral evaluation (DAS) and then uses the iterative procedure GERG88.--

---

On Page 28, after the first full paragraph (line 26), please insert the following paragraph:

B12

--At the procedure according to figure 2b a first approach for the values of  $K$  and  $Z_n$  is made, according to the determination of the directly with conventional means measurable quantities of the probe gas as pressure  $p_b$  and temperature  $T_b$  at operating conditions as well as of the evaluation of the spectrum by means of the direct spectral evaluation (DAS), which at most easy can be drawn from a characteristic diagram, that represents the influence of pressure  $p_b$  at operating conditions and temperature  $T_b$  at operation condition for a known composition of gas similar to the probe gas. With these quantities then for the first time according to the standard-arithmetic procedure GERG88 the respective input quantities of the respective standard-calculation procedure will be calculated and these are then used in the respective iterative procedure. As a result of this a value for the compressibility factor  $K$  is obtained as well as the here from calculatable quantities standard calorific value  $H_{v,n}$  and standard density  $\rho_n$ . Converges the compressibility factor  $K$ , and if necessary also the standard calorific value  $H_{v,n}$  and standard density  $\rho_n$ , towards a final value, than the calculation of the wanted quantities is completed,

B2  
concl'd

because these are now directly available respectively can itself be calculated by means of the calculated values for the compressibility factor K. Is there however no convergence to be ascertained, than the result of the compressibility factor K is put back again into the input quantities of the standard-arithmetic procedure GERG88 and with these changed input quantities the iteration is started once again and after passing through the steps of the procedure once again examined for convergence. Doing this beside the convergence of the value of the compressibility factor K, like this is represented in the figures 2a and 2b, additionally also the convergence of the quantities evaluable from the compressibility coefficient K, for example standard calorific value  $H_{v,n}$  and standard density  $\rho_n$ , can be examined and be utilised as further criterion for termination of the iteration.--

---

On Pages 28-29, for the paragraph bridging pages 28-29, please substitute the following paragraph:

---

B13

--In the following figures 4 to 10 are outlined now advantageous embodiments of the device according to the invention. Same numerals indicate respectively identical or functionally similar devices, so that in the figures 4 to 10. In essence only the differences in the respective embodiments are represented and otherwise is referred to the respective above mentioned description.--

---

On Page 30, for the first full paragraph, please substitute the following paragraph:

---

B14

--In a first conceivable embodiment of the invention according to figure 4 the device is coupled by means of optical fibres 19 to the probe cell 3 and can like this be installed in an

B14  
concluded

explosion-free room behind an explosion barrier 20, while the intrinsic measuring cell itself is located near the gas conduit 18 within not explosion free room. For the recording of a null spectrum and in doing so the offset-transmission of the optical system the probe cell 3 can be filled with a spectroscopical inactive inert gas 23, in infrared for example nitrogen. Alternatively the probe cell 3 can be admitted in addition with a calibrating gas 24 for the verification of the measurement values. Null- and calibrating measurement are carried out in appropriate selected time intervals and are controlled via a valve block 25 by the computational unit 10. This embodiment can also be combined with the other implementations.--

---

On Pages 30-31, for the paragraph bridging pages 30-31, please substitute the following paragraph:

---

B15

--The device presented in the figure 5 works in combination with a prism- or grating-spectrometer, as well as provided in the embodiment according to the state of art according to figure 3. The selection of the wavelength is done thereby not by means of movements of a prism or of the grating or of the radiation receiver 7, instead by a in a chopper arrangement 28 provided with a sector aperture 46. This sector aperture 46 owns free sectors 30, which sequential set free areas of the outlet slit of the grating 47 or the same and with it selected regions of wavelengths of the spectrum of the measurement radiation 8. A projection lens 22 maps the transmitted measurement radiation 8 to a radiation receiver 7; based on the slit-like geometry for the projection lens 22 for example a cylindrical lens will be the best opportunity. With the information of the position of the rotational direction 29 of the rotating aperture 46 and therewith of the wavelength the computational unit 10 determines a simplified transmission spectrum, which is evaluated with the above presented procedure. By the selection of the position and width of the

B5  
Concl'd

sectors 30 regions of wavelengths can be selected, which are optimised for the above presented evaluation procedures, particularly for DSA. The computational unit 10 controls with signals 27 also the rotational movement of the aperture 46. An alternative type design of the chopper arrangement 28 according to claim 12 is represented in the figure 6. The chopper arrangement 28 acts appropriately to sector aperture 46 of the figure 5, whereby however not sequential fixed wavelength intervals are faded in, instead the spectrum rather gets scanned continuously by a spiral slit opening 31 arranged in the aperture 46. The advantage is thereby a superior flexibility for the evaluation of the spectrums, however the measurement time for every interval of wavelength is shortened and in doing so the signal-noise is increased. As with the chopper arrangement 28 according to figure 5 the computational unit 10 ascertains based on the position of the aperture 46 the respective present wavelength and in doing so records a transmission spectrum for the above evaluation procedures MVA and DSA.--

---

On Page 35, for the paragraph on this page, please substitute the following paragraph:

B1b

--The figures 4 to 11 show in a very simplified representation an equipment basic design of a device according to [the claims 55 or 66] claim 98. In this the description is restricted to the essential courses of the procedures and thereto necessary devices. It can be understood, that the expert can carry out with the teachings according to the invention according to the claims a large number of variations and adaptations, that also are covered by the item of the invention.--
